## Floating extensions cylinders

Each extension cylinder is mounted with a “floating type support”, a concept developed by EFFER since 1990.

This allows each cylinder to “float” irrespective of the next one.

When the boom or fly-jib are fully extended, the cylinders remain tangential to the boom camber, instead of being forced to follow it. This feature guarantees that while retracting or extending the boom under a load the extensions rod will always stay lined up to the barrel, preventing an early wear of the gaskets.
